(where the indolinyl nitrogen is meta to the oxazolidinone nitrogen) both generically, see formula (I) where "X" is  $\text{NR}_6$  and specifically see Example 13. The indolinylloxazolidinones of the present invention are 5'-indolinylloxazolidinones (where the indolinyl nitrogen is para to the oxazolidinone nitrogen). Further, WANG discloses aminomethyl-oxoxazolidinyl cycloalkylbenzene derivatives including cycloalkyl-, alkanone-, hydroxycycloalkyl-, oxime-, amine- and other phenyl-oxazolidinones which possess antibacterial activity. More particularly, WANG discloses alkanone or indanone oxazolidinones generally, see formula (I) where  $\text{R}_1$  and  $\text{R}_2$  taken together are -O and specifically, see Examples 16, 26 and 30. All the indanoneoxazolidinones disclosed by WANG require the ketone (-CO-) to be attached directly to the phenyl ring in a position para to the oxazolidinone nitrogen. The indanoneoxazolidinones (XXIB) of the present invention differ from those of WANG. WANG also discloses oximinooxazolidinones, see Example 21 as well as the generic disclosure for  $\text{R}_1$  and  $\text{R}_2$  taken together to be -NOH.

#### DETAILED DESCRIPTION OF THE INVENTION

The 5'-indolinylloxazolidin-2-ones (XI) are prepared starting with the corresponding 5-nitroindolines (I). It is preferred that  
15 R<sub>2</sub>, R<sub>3</sub> and R<sub>4</sub> all be -H. The indolinyl nitrogen of the 5-nitroindolines (I) is protected to produce the corresponding protected 5-nitroindolines (II). Suitable protecting agents, X<sub>1</sub>, include t-butyloxycarbonyl (BOC), acetyl, -CO-O-CH<sub>2</sub>-φ and -CO-O-(CH<sub>2</sub>)<sub>2</sub>-Si(CH<sub>3</sub>)<sub>3</sub>. It is preferred that X<sub>1</sub> be t-butyloxycarbonyl. Next, the  
20 nitro group of the protected 5-nitroindolines (II) is reduced with hydrogen and an appropriate catalyst such as palladium on carbon to the corresponding protected 5-aminoindolines (III). Acylation of the free unprotected 5-amino group of the 1-protected 5-aminoindolines (III) with a carbobenzyloxy (CBZ) group gives the urethanes (IV).  
25 The urethanes (IV) are then reacted with Br-CH<sub>2</sub>-CH=CH<sub>2</sub> in THF and a base forming the N-allyl-N-CBZ compounds (V). Suitable bases include sodium hydride, sodium methoxide, potassium tertiary butoxide and lithium diisopropylamide; preferred is sodium hydride. The N-allyl-N-CBZ compounds (V) are cyclized to form the oxazolidinone nucleus by  
30 reaction with an electrophilic agent. Suitable electrophilic agents include bromine and iodine; iodine in chloroform is preferred. The oxazolidinone nucleus formed is the protected 5-iodomethyloxazolidin-2-one (VI). Following formation of the oxazolidinone ring, the desired side chain at the 5-position is formed by reacting the  
35 protected 5-iodomethyl oxazolidinones (VI) with an azide to form the protected azides (VII). The protected azides (VII) are reduced with hydrogen in the presence of a catalyst such as palladium or by Pφ<sub>3</sub> or

-16-

H<sub>2</sub>S or other methods known to those skilled in the art to give racemic protected 5-aminomethyloxazolidin-2-ones (VIII). The racemic compounds can be resolved at the aminomethyloxazolidinone (VIII) stage using methods known to those skilled in the art, see for example, Optical Resolution Procedures for Chemical Compounds, Vol 1, : Amines and Related Compounds, Paul Newman, Optical Resolution Information Center, Manhattan College, Riverdale, NY, 10471, 1978. For example, treatment of the d,l-aminomethyloxazolidinone (VIII) mixture with an optically active acid such as (+)-tartaric acid or alternatively with (-)-tartaric acid, would yield a mixture of diastereomeric salts, which can be separated most conveniently by fractional crystallization to give a salt containing only one enantiomer of the racemic mixture. Other suitable optically active acids include, (-) dibenzoyltartaric acid, (+)-camphoric acid, (+)- and (-)-malic acid and (+)-camphor-10-sulfonic acid. By reacting the diastereomeric salt with a base one obtains the enantiomer as the free compound. These compounds are then acylated to produce the protected 5'-indolinyloxazolidin-2-ones (IX) containing the desired R<sub>1</sub> group. It is preferred that R<sub>1</sub> is H, C<sub>1</sub>-C<sub>6</sub> alkyl, C<sub>3</sub>-C<sub>6</sub> cycloalkyl, -OCH<sub>3</sub> and -CHCl<sub>2</sub>; it is more preferred that R<sub>1</sub> is -CH<sub>3</sub>. Acid hydrolysis of the (BOC) protected 5'-indolinyloxazolidin-2-ones (IX) produces the unprotected 5'-indolinyloxazolidin-2-ones (X) which are then N-acylated or N-alkylated, if necessary, with the desired R<sub>5</sub> group, either as the acid halide, anhydride, or through a reductive alkylation sequence to produce the desired 5'-indolinyloxazolidin-2-ones (XI). The CBZ protecting group is removed by hydrogen with palladium on carbon and the -CO-O-(CH<sub>2</sub>)<sub>2</sub>-Si(CH<sub>3</sub>)<sub>3</sub> is removed by tetra-butylammonium fluoride, see J. Chem. Soc. Chem. Commun., 358 (1970). For the 5'-indolinyloxazolidin-2-ones (XI), it is preferred that R<sub>5</sub> is -CH<sub>3</sub>, -CH<sub>2</sub>-CH=CH<sub>2</sub>, -CH<sub>2</sub>-C=CH, -CHO, -CO-R<sub>5-1</sub> where R<sub>5-1</sub> is -CH<sub>3</sub>, -C<sub>2</sub>H<sub>5</sub>, -CH(CH<sub>3</sub>)<sub>2</sub>, -CH<sub>2</sub>Cl, -CHCl<sub>2</sub>, -CH<sub>2</sub>-OH, -CH<sub>2</sub>-O-CH<sub>3</sub>, 2-thienyl and cyclopropyl. It is more preferred that R<sub>5</sub> is -CH<sub>3</sub>, -CH<sub>2</sub>-CH=CH<sub>2</sub>, -CHO, -CO-R<sub>5-1</sub> where R<sub>5-1</sub> is -CH<sub>3</sub>, -C<sub>2</sub>H<sub>5</sub>, -CHCl<sub>2</sub>, -CH<sub>2</sub>-OH and 2-thienyl.

35 The 3-(fused-ring substituted)phenyl-5β-amidomethyloxazolidin-2-ones (XXI) are prepared by methods known to those skilled in the art from known starting compounds. See, for example, European Patent

-17-

Publications 127,902 and 184,170; Antimicrobial Agents and Chemotherapy 1791 (1987) and Tetrahedron 43, 2505 (1987).

The 3-(fused-ring substituted)phenyl-5 $\beta$ -amidomethyloxazolidin-2-ones (XXI) of the present invention include the fused alkanonephenyl-oxazolidinones (B), the fused cycloalkenylphenyloxazolidinones (D), and the fused oximinocycloalkylphenyl-oxazolidinones (E), see CHART C. It is preferred that the 3-(fused-ring substituted)phenyl-5 $\beta$ -amidomethyloxazolidinones (XXI) are the fused alkanonephenyloxazolidinones (B) and the fused oximinocycloalkylphenyloxazolidinones (E). It is more preferred that the 3-(fused-ring substituted)phenyl-5 $\beta$ -amidomethyloxazolidin-2-ones (XXI) are the fused alkanonephenyl-oxazolidin-2-ones (B).

The oxazolidinone nucleus is formed by starting with an appropriately substituted aniline (XV) containing the desired R<sub>2</sub>/R<sub>3</sub>/R<sub>4</sub> moiety (see CHART C) or one which can readily be transformed to the desired moiety. The oxazolidinone ring system is synthesized after protecting the aniline (XV) nitrogen with a carbobenzyloxy (CBZ) group. Acylation of the aniline (XV) nitrogen atom gives the urethane (XVI). The urethane (XVI) is then reacted with Br-CH<sub>2</sub>-CH=CH<sub>2</sub> in THF and a base forming an N-allyl-N-CBZ compound (XVII). Suitable bases include sodium hydride, sodium methoxide, potassium tertiary butoxide and lithium diisopropylamide; preferred is sodium hydride. The N-allyl-N-CBZ compound (XVII) is cyclized to form the oxazolidinone nucleus by reaction with an electrophilic agent. Suitable electrophilic agents include bromine and iodine; iodine in chloroform is preferred. The oxazolidinone nucleus formed is the 5-iodomethyloxazolidin-2-one (XVIII). When the phenyl substituent contains a chiral center then the oxazolidinone ring has two different substituents at the C<sub>5</sub> position and therefore produces two diastereomers. These can be separated by crystallization or chromatography. Following formation of the oxazolidinone ring, the desired side chain at the 5-position is formed by reacting the iodomethyloxazolidin-2-one (XVIII) with an azide to form the azide (XIX). The azide is reduced with hydrogen in the presence of a catalyst such as palladium or by P $\phi$ <sub>3</sub> or H<sub>2</sub>S or other methods known to those skilled in the art to give the 5-aminomethyl oxazolidinone as the N-appropriately substituted-3-phenyl-5-aminomethyloxazolidin-2-

-18-

one (XX). This compound is then acylated to give the desired  $R_1$  group. It is preferred that  $R_1$  is -H,  $C_1$ - $C_6$  alkyl,  $C_3$ - $C_6$  cycloalkyl, -OCH<sub>3</sub>, -CHCl<sub>2</sub> and -CH<sub>2</sub>Cl; it is more preferred that  $R_1$  is -CH<sub>3</sub>.

5 This process is operative regardless of whether the 3-(fused-ring substituted)phenyl-5-amidomethyloxazolidin-2-one (XXI) has a five or six member ring attached to the phenyl group.

Both the 2,3- and 3,4- indanyl (5 member alkyl ring) and the 2,3- and 3,4- six member alkyl rings of the fused cycloalkylphenyloxazolidin-2-ones (XXIA), are prepared by starting with the appropriately substituted aniline (XVA). It is preferred that  $n_2$  is 3 or 4.

10 The 2,3- and 3,4- fused alkanonephenyloxazolidin-2-ones (XXIB), are prepared following the procedure for the preparation of the fused cycloalkylphenyloxazolidin-2-ones (XXIA). The alkyl aniline intermediate (XVA) is first oxidized to the corresponding alkanone aniline (XVB) by known procedures. See for example, J. Org. Chem., 27, 70 (1962). The amino group is protected, for example as the acetamide, and then the protected aniline (XVA) is oxidized to the corresponding protected alkanone aniline (XVB) with an oxidizing agent such as chromium trioxide in acetic acid and acetone. The deprotected alkanonephenyl aniline (XVB) is then reacted just as the corresponding alkyl aniline (XVA) to produce the corresponding alkanone (XXIB). It may be necessary to protect the ketone functionality as the ketal with ethylene glycol, for example, followed by deprotection with acid treatment at a later-stage. For the 3,4- substitution, with a para ketone, with either the 5 or 6 member ring, alternatively and preferably, the fused cycloalkylphenyloxazolidin-2-one (XXIA) product can be oxidized with an oxidizing agent such as chromium trioxide in acetic acid and acetic anhydride directly to the corresponding fused alkanonephenyloxazolidin-2-one (XXIB) product. When the ketone ring has a substituent on the carbon atom next to the carbonyl group (either  $R_{10-1}$ ,  $R_{10-2}$ ,  $R_{10-3}$  or  $R_{10-4}$  is not -H) the compounds are prepared by either starting with the appropriately substituted aniline intermediate (XVB) or by alkylation of the ketone (XXIB) or enamine (XXIH) at a later stage in the synthesis as is known to those skilled in the art. When the alkylation reaction is performed, it produces both the mono- and dialkylated products. If

15  
20  
25  
30  
35

-19-

the alkanonephenyloxazolidin-2-one (XXIB) is alkylated; it is preferred that the alkanonephenyloxazolidin-2-one (XXIB) be mono-alkylated rather than dialkylated. It is preferred that  $n_3 + n_4 + n_7 + n_8 = 2$  or 3. It is preferred that  $R_{10-3}$  is  $-CH_3$  or  $-CH_2-OH$  and where  $R_{10-3}$  and  $R_{10-4}$  are taken together to form cyclopropyl. It is more preferred that  $R_{10-1}$  is  $-CH_3$ .

The fused hydroxycycloalkylphenyloxazolidin-2-ones (XXIC) are prepared from the corresponding fused alkanonephenyloxazolidin-2-ones (XXIB) by reduction with a reducing agent such as sodium borohydride, sodium cyanoborohydride, lithium borohydride, lithium tri-sec-butylborohydride, etc. The reduction of the ketone to the corresponding secondary alcohol produces two diastereomers which can be separated by chromatography or crystallization. Both of the diastereomers have the desired antibacterial activity, though in some cases to different degrees. It is preferred that  $n_3 + n_4 = 2$  or 3. Treatment of the alcohol with a base such as sodium hydride in the presence of an alkylating agent such as an alkyl iodide or epoxide, results in the formation of the corresponding ether,  $-CH(-OR)-$ , as is known to those skilled in the art. The fused cycloalkenylphenyloxazolidin-2-ones (XXID) are preferably produced by the procedure of CHART D starting with the desired amino indene or amino dihydronaphthalene (XVID). Alternatively, the indenenes (XXID) are produced by dehydration (alcohol elimination) of the corresponding indanol (XXIC). Suitable reagents for the dehydration include  $(CF_3-CO)_2O$ ,  $CH_3-SO_2-Cl$  or  $(CF_3SO_2)_2O$  and triethylamine. Dehydration of a benzylic substituted fused hydroxycycloalkylphenyloxazolidinone (C) will result in the production of just one fused cycloalkenylphenyloxazolidinone (D). However, with a non-benzylic fused hydroxycycloalkylphenyloxazolidinone (C), two dehydration products are produced. Both are within the scope of the invention. It is preferred that  $n_5 + n_6 = 1$  or 2.

The fused oximinocycloalkylphenyloxazolidin-2-ones (XXIE) are prepared from the corresponding fused alkanonephenyloxazolidin-2-ones (XXIB) by reaction with hydroxylamine ( $R_7$  is  $-H$ ) hydrochloride or a substituted hydroxylamine ( $R_7$  is not  $-H$ ) hydrochloride in the presence of a base such as pyridine or sodium bicarbonate.

Once the aminomethyloxazolidin-2-ones (XX) are obtained various

-20-

analogues and/or derivatives can readily be prepared by acylation. For pharmacological activity it is necessary that the 5-amidomethyl side chain be in the  $\beta$  configuration; hence, the -H at C<sub>5</sub> must be in the  $\alpha$  configuration. It is preferred that R<sub>1</sub> be -CH<sub>3</sub> and -OCH<sub>3</sub>,

5 -CHCl<sub>2</sub> and C<sub>3</sub>-C<sub>6</sub> cycloalkyl; it is more preferred that R<sub>1</sub> be -CH<sub>3</sub>.

The synthesis of the indazolyloxazolidin-2-ones (XXXII) starts with the appropriate nitroindazole (XXII). It is preferred that R<sub>2</sub>, R<sub>3</sub> and R<sub>4</sub> all be -H. It is preferred that R<sub>6</sub> is -H or -CH<sub>3</sub>. The indazolyl nitrogen of the nitroindazoles (XXII) is protected, as  
10 previously discussed, to produce the corresponding protected nitroindazoles (XXIII). It is preferred that X<sub>1</sub> be t-butyloxycarbonyl. Next, the nitro group of the protected nitroindazoles (XXIII) is reduced with hydrogen, as previously discussed, to the corresponding protected aminoindazoles (XXIV). Acylation of free unprotected amino  
15 group of the protected aminoindazoles (XXIV) with a carbobenzyloxy (CBZ) group gives the urethanes (XXV). The urethanes (XXV) are then reacted with Br-CH<sub>2</sub>-CH=CH<sub>2</sub> in THF and a base, as previously discussed, forming the protected allyl compounds (XXVI) and the bisallyl compounds (XXVI'). The protected allyl compounds (XXVI) and the  
20 bisallyl compounds (XXVI') can be separated at this point but it is preferable to use the mixture as the starting material for the next step. The protected allyl compounds (XXVI) and the bisallyl compounds (XXVI') are cyclized to form the oxazolidinone nucleus by reaction with an electrophilic agent, as previously discussed. The  
25 oxazolidinone nuclei formed are the protected iodomethyloxazolidin-2-ones (XXVII) and the allyliodomethyloxazolidin-2-ones (XXVII'). Following formation of the oxazolidinone ring, the desired side chain at the 5-position is formed, as previously discussed, to form the azides (XXVIII) and allylazides (XXVIII'). During the reaction of  
30 the iodomethyl compounds (XXVII/XXVII') to the corresponding azides (XXVIII/XXVIII') the protecting group, X<sub>1</sub>, of the iodomethyl compounds (VI) may be lost, see CHART E. In other cases it will be retained and can be removed after the aminomethyl group is acylated. The azides (XXVIII) and allylazides (XXVIII') can be separated but it  
35 is preferred to not separate them at this stage but to reduce the mixture. The azides (XXVIII) and allylazides (XXVIII') are reduced with hydrogen, as previously discussed, to give aminomethyloxazoli-

-21-

din-2-ones (XXIX) and 3-allyl-5-aminomethyloxazolidin-2-ones (XXIX').

When the oxazolidinone nucleus is formed to give compounds (XXVII and XXVII') an asymmetric center is created at C<sub>5</sub> which gives rise to a racemic mixture. It is preferable to resolve the racemic mixture, if desired, at the aminomethyloxazolidin-2-one (XXIX) and allylaminomethyloxazolidin-2-one (XXIX') stage using methods known to those skilled in the art, as previously discussed.

The aminomethyloxazolidin-2-ones (XXIX) and allylaminomethyloxazolidin-2-ones (XXIX') are then acylated to produce the protected indazolyloxazolidin-2-ones (XXX), unprotected indazolyloxazolidin-2-ones (XXXI) and allyl indazolyloxazolidin-2-ones (XXX') containing the desired R<sub>1</sub> group at C<sub>5</sub>. In the case of the indazolyloxazolidin-2-ones (XXX) the acylation produces the bis acylated compound with the acyl group also at the 1-indazolyl position. In most cases this will be a desired product and therefore is in the scope of the claimed indazolyloxazolidin-2-ones (XXXII). The allyl indazolyloxazolidin-2-ones (XXXII') are useful pharmacological agents and intermediates within the scope of the indazolyloxazolidin-2-ones (XXXII). It is preferred that R<sub>1</sub> is H, C<sub>1</sub>-C<sub>6</sub> alkyl, C<sub>3</sub>-C<sub>6</sub> cycloalkyl, -OCH<sub>3</sub> and -CHCl<sub>2</sub>; it is more preferred that R<sub>1</sub> is -CH<sub>3</sub>.

In the cases where the protecting group, X<sub>1</sub>, was not cleaved by azide the protecting group is then removed, for example, by trifluoroacetic acid treatment to give the unprotected indazolyloxazolidin-2-ones (XXXI).

The unprotected indazolyloxazolidin-2-ones (XXXI) are then N-acylated or N-alkylated, if necessary, with the desired R<sub>5</sub> group, either as the acid halide, anhydride, or alkyl halide to produce the desired indazolyloxazolidin-2-ones (XXXII). For the indazolyloxazolidin-2-ones (XXXII), it is preferred that R<sub>5</sub> is selected from the group consisting of -CH<sub>3</sub>, -CH<sub>2</sub>-CH=CH<sub>2</sub>, -CH<sub>2</sub>-C=CH, -CHO, -CO-R<sub>5-1</sub> where R<sub>5-1</sub> is -CH<sub>3</sub>, -C<sub>2</sub>H<sub>5</sub>, -CH(CH<sub>3</sub>)<sub>2</sub>, -CHCl<sub>2</sub>, -CH<sub>2</sub>-OH, -CH<sub>2</sub>-O-CH<sub>3</sub>, 2-thiophene and cyclopentyl. It is more preferred that R<sub>5</sub> is -CH<sub>3</sub>, -CH<sub>2</sub>-CH=CH<sub>2</sub>, -CHO, -CO-R<sub>5-1</sub> where R<sub>5-1</sub> is -CH<sub>3</sub>, -C<sub>2</sub>H<sub>5</sub>, -CHCl<sub>2</sub>, -CH<sub>2</sub>-CN, -CH<sub>2</sub>-OH, -CH<sub>2</sub>-O-CH<sub>3</sub>, -CH<sub>2</sub>-O-CO-CH<sub>3</sub>, -CH<sub>2</sub>-O-CH<sub>2</sub>-φ or 2-thiophene.

The benzimidazolyloxazolidin-2-ones (XLIII) and the benzotriazolyloxazolidin-2-ones (LIV) are prepared in a similar manner (compare CHARTS F and G) to the indazolyloxazolidin-2-ones (XXXII)

-22-

(CHART E) with the following exceptions. First, with the indazolyl compounds when transforming the urethane (XXV) to the protected allyl compound (XXVI), the allyl group replaced the protecting group ( $X_1$ ) to some extent producing the bisallylindazolyl compounds (XXVI'); with the benzimidazolyloxazolidin-2-ones (XLI) and the benzotriazolyloxazolidin-2-ones (LIV) the  $X_1$  protecting group is not lost when transforming the urethanes (XXXVI and XLVII) to the protected compounds (XXXVII and XLVIII) respectively. Second, with the indazolyl compounds when reducing the azide (XXVIII) with hydrogen again the protecting group is lost producing the aminomethyl compounds (XXIX); with the benzimidazolyloxazolidin-2-ones (XLI) and the benzotriazolyloxazolidin-2-ones (LIV) the protecting group  $X_1$  is not lost when reducing the protected azides (XXXIX and L) respectively.

In producing the benzimidazolyloxazolidin-2-ones (XLI), in many cases the desired  $R_5$  group of the benzimidazolyloxazolidin-2-ones (XLI) may be the same as the protecting group  $X_1$  in the intermediate precursors (XXXIV-XLI). In those cases the protected benzimidazolyloxazolidin-2-ones (XLI) are identical to the benzimidazolyloxazolidin-2-ones (XLI), and therefore one has obtained the useful end product when obtaining the protected benzimidazolyloxazolidinones (XLI).

For the benzimidazolyloxazolidin-2-ones (XLI) it is preferred that  $R_6$  is -H or  $C_1$ - $C_6$  alkyl.

The 5'-indolinyloxazolidin-2-ones (XI), the 3-(fused-ring substituted)phenyl-5 $\beta$ -amidomethyloxazolidin-2-ones (XXI), the indazolyl-oxazolidin-2-ones (XXXII), the benzimidazolyloxazolidin-2-ones (XLI) and the benzotriazolyloxazolidin-2-ones (XLIV) all have an asymmetric center at the  $C_5$ -position of the oxazolidinone ring which produces two enantiomers. The mixture of enantiomers is resolved by means known to those skilled in the art. The enantiomer which is pharmacologically active is the  $\beta$ -enantiomer, see CHARTS A thru G. The racemic mixture is useful in the same way and for the same purpose as the pure  $\beta$ -enantiomer; the difference is that twice as much racemic material must be used to produce the same effect as the pure  $\beta$ -enantiomer.

For convenience the indazolylloxazolidin-2-ones (XXXII), ben-

-23-

zimidazolyloxazolidin-2-ones (XLIII) and benzotriazolyloxazolidin-2-ones (LIV) will be collectively referred to as the 3-(nitrogen substituted)phenyl-5 $\beta$ -amidomethylloxazolidin-2-ones (LV).

5 The 5'-indolinyloxazolidin-2-ones (XI), 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) of the present invention are useful as antibacterial agents in treating infections in mammals caused by gram-positive and anaerobic infections. It is preferred to treat humans and useful warm-blooded  
10 mammals such as cattle, horses, sheep, hogs, dogs, cats, etc.

The 5'-indolinyloxazolidin-2-ones (XI), 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) of the present invention are also useful in treating AIDS patients  
15 infected with *Mycobacterium avium*.

The 5'-indolinyloxazolidin-2-ones (XI), 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) can be administered either parenterally (IV, IM, SQ) or orally. The  
20 daily dose is about 5 to about 20 mg/kg. This dose can preferably be given in divided doses and administered 2-4 times daily. The preferred route of administration as well as the particular dosage form for either the parenteral or oral route depends on the particular facts of the situation including the nature of the infection  
25 and condition of the patient. The usual pharmaceutical dosage forms appropriate for parenteral (solution, suspension in oil) and oral (tablet, capsule, syrup, suspension, etc) administration are known to those skilled in the art and there is nothing unusual about using those dosage forms with the 5'-indolinyloxazolidin-2-ones (XI), the  
30 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV). The exact dosage of the 5'-indolinyloxazolidin-2-ones (XI), the 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) to be administered, the frequency  
35 of administration, route of administration, the dosage form will vary depending on a number of factors known to those skilled in the art

-24-

including the age, weight, sex, general physical condition of the patient, the nature of the infection (particular microorganism involved, its virulence, the extent of the infection) other medical problems of the patient, etc as is well known to the physician treating infectious diseases.

The 5'-indolinyloxazolidin-2-ones (XI), the 3-(fused-ring substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) can be used either alone or in conjunction with other antibacterial agents as is known to those skilled in the art. Further, the 5'-indolinyloxazolidin-2-ones (XI), the 3-(fused-ring substituted)-phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (XXI) and the 3-(nitrogen substituted)phenyl-5 $\beta$ -(amidomethyl)oxazolidin-2-ones (LV) can be used in conjunction with non-antibacterial agents as is known to those skilled in the art.

Suitable pharmaceutically acceptable salts include, for example, chloride, sulfate, phosphate, citrate and oxylate.

#### DEFINITIONS AND CONVENTIONS

The definitions and explanations below are for the terms as used throughout this entire document including both the specification and the claims.

##### I. CONVENTIONS FOR FORMULAS AND DEFINITIONS OF VARIABLES

The chemical formulas representing various compounds or molecular fragments in the specification and claims may contain variable substituents in addition to expressly defined structural features. These variable substituents are identified by a letter or a letter followed by a numerical subscript, for example, "Z<sub>i</sub>" or "R<sub>i</sub>" where "i" is an integer. These variable substituents are either monovalent or bivalent, that is, they represent a group attached to the formula by one or two chemical bonds. For example, a group Z<sub>1</sub> would represent a bivalent variable if attached to the formula CH<sub>3</sub>-C(=Z<sub>1</sub>)H. Groups R<sub>1</sub> and R<sub>j</sub> would represent monovalent variable substituents if attached to the formula CH<sub>3</sub>-CH<sub>2</sub>-C(R<sub>1</sub>)(R<sub>j</sub>)H<sub>2</sub>. When chemical formulas are drawn in a linear fashion, such as those above, variable substituents contained in parentheses are bonded to the atom immediately to the left of the variable substituent enclosed in parenthesis. When two or more consecutive variable substituents are enclosed in

-25-

parentheses, each of the consecutive variable substituents is bonded to the immediately preceding atom to the left which is not enclosed in parentheses. Thus, in the formula above, both  $R_i$  and  $R_j$  are bonded to the preceding carbon atom.

5 Chemical formulas or portions thereof drawn in a linear fashion represent atoms in a linear chain. The symbol "-" in general represents a bond between two atoms in the chain. Thus  $\text{CH}_3\text{-O-CH}_2\text{-CH(R}_i\text{)-CH}_3$  represents a 2-substituted-1-methoxypropane compound. In a similar fashion, the symbol "=" represents a double bond, e.g.,  
10  $\text{CH}_2\text{=C(R}_i\text{)-O-CH}_3$ , and the symbol "=" represents a triple bond, e.g.,  $\text{HC}\equiv\text{C-CH(R}_i\text{)-CH}_2\text{-CH}_3$ . Carbonyl groups are represented in either one of two ways: -CO- or -C(=O)-, with the former being preferred for simplicity.

Chemical formulas of cyclic (ring) compounds or molecular  
15 fragments can be represented in a linear fashion. Thus, the compound 4-chloro-2-methylpyridine can be represented in linear fashion by  $\text{N}^*\text{-C(CH}_3\text{)-CH-CCl-CH-C}^*\text{H}$  with the convention that the atoms marked with an asterisk (\*) are bonded to each other resulting in the formation of a ring. Likewise, the cyclic molecular fragment, 4-  
20 (ethyl)-1-piperazinyl can be represented by  $\text{-N}^*\text{-(CH}_2\text{)}_2\text{-N(C}_2\text{H}_5\text{)-CH}_2\text{-C}^*\text{H}_2$ .

A rigid cyclic (ring) structure for any compounds herein defines an orientation with respect to the plane of the ring for substituents attached to each carbon atom of the rigid cyclic compound. For  
25 saturated compounds which have two substituents attached to a carbon atom which is part of a cyclic system, -C( $X_1$ )( $X_2$ )- the two substituents may be in either an axial or equatorial position relative to the ring and may change between axial/equatorial. However, the position of the two substituents relative to the ring and each other  
30 remains fixed. While either substituent at times may lie in the plane of the ring (equatorial) rather than above or below the plane (axial), one substituent is always above the other. In formulas depicting such compounds, a substituent ( $X_1$ ) which is "below" another substituent ( $X_2$ ) will be identified as being in the alpha ( $\alpha$ )  
35 configuration and is identified by a broken, dashed or dotted line attachment to the carbon atom, i.e., by the symbol "- - -" or "...". The corresponding substituent attached "above" ( $X_2$ ) the other ( $X_1$ ) is

-26-

identified as being in the beta ( $\beta$ ) configuration and is indicated by an unbroken line attachment to the carbon atom.

When a variable substituent is bivalent, the valences may be taken together or separately or both in the definition of the variable. For example, a variable  $R_i$  attached to a carbon atom as  $-C(-R_i)-$  might be bivalent and be defined as oxo or keto (thus forming a carbonyl group  $(-CO-)$  or as two separately attached monovalent variable substituents  $\alpha-R_{i-j}$  and  $\beta-R_{i-k}$ . When a bivalent variable,  $R_i$ , is defined to consist of two monovalent variable substituents, the convention used to define the bivalent variable is of the form " $\alpha-R_{i-j}:\beta-R_{i-k}$ " or some variant thereof. In such a case both  $\alpha-R_{i-j}$  and  $\beta-R_{i-k}$  are attached to the carbon atom to give  $-C(\alpha-R_{i-j})(\beta-R_{i-k})-$ . For example, when the bivalent variable  $R_6$ ,  $-C(-R_6)-$  is defined to consist of two monovalent variable substituents, two monovalent variable substituents are  $\alpha-R_{6-1}:\beta-R_{6-2}$ , ....  $\alpha-R_{6-9}:\beta-R_{6-10}$ , etc; giving  $-C(\alpha-R_{6-1})(\beta-R_{6-2})-$ , ....  $-C(\alpha-R_{6-9})(\beta-R_{6-10})-$ , etc. Likewise, for the bivalent variable  $R_{11}$ ,  $-C(-R_{11})-$ , two monovalent variable substituents are  $\alpha-R_{11-1}:\beta-R_{11-2}$ . For a ring substituent for which separate  $\alpha$  and  $\beta$  orientations do not exist (e.g. due to the presence of a carbon carbon double bond in the ring), and for a substituent bonded to a carbon atom which is not part of a ring the above convention is still used, but the  $\alpha$  and  $\beta$  designations are omitted.

Just as a bivalent variable may be defined as two separate monovalent variable substituents, two separate monovalent variable substituents may be defined to be taken together to form a bivalent variable. For example, in the formula  $-C_1(R_i)H-C_2(R_j)H-$  ( $C_1$  and  $C_2$  define arbitrarily a first and second carbon atom, respectively)  $R_i$  and  $R_j$  may be defined to be taken together to form (1) a second bond between  $C_1$  and  $C_2$  or (2) a bivalent group such as oxa  $(-O-)$  and the formula thereby describes an epoxide. When  $R_i$  and  $R_j$  are taken together to form a more complex entity, such as the group  $-X-Y-$ , then the orientation of the entity is such that  $C_1$  in the above formula is bonded to  $X$  and  $C_2$  is bonded to  $Y$ . Thus, by convention the designation "...  $R_i$  and  $R_j$  are taken together to form  $-CH_2-CH_2-O-CO-$  ..." means a lactone in which the carbonyl is bonded to  $C_2$ . However, when designated "...  $R_j$  and  $R_i$  are taken together to form  $-CH_2-CH_2-O-CO-$ "

-27-

the convention means a lactone in which the carbonyl is bonded to C<sub>1</sub>.

The carbon atom content of variable substituents is indicated in one of two ways. The first method uses a prefix to the entire name of the variable such as "C<sub>1</sub>-C<sub>4</sub>", where both "1" and "4" are integers representing the minimum and maximum number of carbon atoms in the variable. The prefix is separated from the variable by a space. For example, "C<sub>1</sub>-C<sub>4</sub> alkyl" represents alkyl of 1 through 4 carbon atoms, (including isomeric forms thereof unless an express indication to the contrary is given). Whenever this single prefix is given, the prefix indicates the entire carbon atom content of the variable being defined. Thus C<sub>2</sub>-C<sub>4</sub> alkoxycarbonyl describes a group CH<sub>3</sub>-(CH<sub>2</sub>)<sub>n</sub>-O-CO- where n is zero, one or 2. By the second method the carbon atom content of only each portion of the definition is indicated separately by enclosing the "C<sub>1</sub>-C<sub>j</sub>" designation in parentheses and placing it immediately (no intervening space) before the portion of the definition being defined. By this optional convention (C<sub>1</sub>-C<sub>3</sub>)alkoxy-carbonyl has the same meaning as C<sub>2</sub>-C<sub>4</sub> alkoxycarbonyl because the "C<sub>1</sub>-C<sub>3</sub>" refers only to the carbon atom content of the alkoxy group. Similarly while both C<sub>2</sub>-C<sub>6</sub> alkoxyalkyl and (C<sub>1</sub>-C<sub>3</sub>)alkoxy(C<sub>1</sub>-C<sub>3</sub>)alkyl define alkoxyalkyl groups containing from 2 to 6 carbon atoms, the two definitions differ since the former definition allows either the alkoxy or alkyl portion alone to contain 4 or 5 carbon atoms while the latter definition limits either of these groups to 3 carbon atoms.

EXAMPLE 41       N-(Carbobenzyloxy)-5-aminoindan (XVIA)

Sodium bicarbonate (7.20 g) is added to a solution of 5-amino-  
indan (XVA, 5.71 g) in acetone (60 ml) and water (30 ml) 0°, followed  
by the dropwise addition of benzylchloroformate (6.8 ml, 8.07 g) over  
5 min. The mixture is stirred at 0° for about 1 hr, then at 20-25°

extract is washed with saturated aqueous sodium bicarbonate, dried  
over magnesium sulfate, and concentrated under reduced pressure to  
give an oil. The oil is purified by column chromatography on 60-200  
μ silica gel, eluting with ethyl acetate/hexane (10/90). The  
appropriate fractions are pooled and concentrated to give the title  
compound, mp 56-59°; NMR (CDCl<sub>3</sub>, 300 MHz) 7.40-7.03, 7.11, 7.05,

with evolution of hydrogen gas. Allyl bromide (3.4 ml, 4.8 g) is then added over 1 min. The mixture is stirred at 20-25° for 1 hr forming a solid. The mixture is then heated at reflux for 3.5 hr then stirred at 20-25° overnight. An aliquot is taken, poured into water and ethyl acetate, and the organic layer evaporated. NMR analysis indicates complete reaction. The mixture is poured into ethyl acetate (300 ml), and washed with water (2 x 250 ml). The combined aqueous layers are extracted with ethyl acetate (100 ml). The combined organic layers are washed with saline, dried over magnesium sulfate and concentrated under reduced pressure to give an oil. The residue is purified by gravity filtration thru a silica gel column (2.5 cm x 10 cm, 60-200  $\mu$ ), eluting with hexane. After stirring an additional 2.25 hr, the mixture is filtered thru diatomaceous earth, washing the pad first with ethyl acetate, then methanol/ethyl acetate (10/90). The filtrate is concentrated under reduced pressure to give a solid. This is deemed of sufficient quality for further use.

35 For an analytical sample, approximately 50 mg is dissolved in chloroform and loaded onto a 2 inch silica gel plug in a pipette. This is eluted with ethyl acetate to remove less polar impurities, then methanol/ethyl acetate (1/1). The eluate is concentrated to
